

## Week 2

### Binary classification

As the name suggests, this classification gives an output in binary form, i.e., 1 or 0.

This is achieved using feature vectors and classifier.

**Feature Vector** - It is an  $n$ -dimensional matrix containing all pixel values from the matrices of the image with red, green and blue pixels. Here,  $n$  is the number of pixel values in total. Each matrix (red, green or blue) has same size as the image.

Eg. Image of size  $64 \times 64$  will give a feature vector with size  $(64 \times 64 \times 3, m)$ , i.e.,  $(n, m)$ .

Here,  $n$  = no of total reshaped or un-rolled pixel values. [Total =  $r+g+b$ ]

$m$  = Training data size

**Training set** : matrix denoted by Capital  $X$  that contains total ' $m$ ' feature vectors;

$X$  is the training set where  $x_1, x_2, \dots, x_m$  are feature vectors

$Y$  is also introduced as stacking data in columns is conventional for implementing neural networks

### **Logistic Regression**

It is an algorithm that is used when we want output labels to be 0 or 1, i.e., binary

Parameters of the algorithm are  $W$  and  $b$ ;  $W$  is  $n$ -dimensional vector and  $b$  is a real number.

Parameters:  $\boxed{w} \in \mathbb{R}^n$ ,  $\boxed{b} \in \mathbb{R}$ .

Output  $\hat{y} = \sigma(\underbrace{w^T x + b}_z)$

$$\sigma(z) = \frac{1}{1 + e^{-z}}$$

If  $z$  large  $\sigma(z) \approx \frac{1}{1+0} = 1$

If  $z$  large negative number

$$\sigma(z) = \frac{1}{1 + e^{-z}} \approx \frac{1}{1 + \text{Big num}} \approx 0$$

$\hat{y}$  is output, and formula for is given in the image in terms of  $w$  and  $b$ ;  $W^T$  is  $w$  transpose

here, sigmoid function is used as it helps to get an output between 0 and 1. Note  $y$  is different for each training example

## Loss function

this function judges a models performance.

Loss (error) function:  $\mathcal{L}(\hat{y}, y) = \frac{1}{2} (\hat{y} - y)^2$

$$\boxed{\mathcal{L}(\hat{y}, y)} = - (y \log \hat{y}) + (1-y) \log(1-\hat{y})$$

If  $y=1$ :  $\mathcal{L}(\hat{y}, y) = -\log \hat{y} \leftarrow$  want  $\log \hat{y}$  large, want  $\hat{y}$  large.

If  $y=0$ :  $\mathcal{L}(\hat{y}, y) = -\log(1-\hat{y}) \leftarrow$  want  $\log(1-\hat{y})$  large ... want  $\hat{y}$  small

$$\boxed{\text{Cost}}$$
 function:  $J(w, b) = \frac{1}{m} \sum_{i=1}^m \mathcal{L}(\hat{y}^{(i)}, y^{(i)}) = -\frac{1}{m} \sum_{i=1}^m [y^{(i)} \log \hat{y}^{(i)} + (1-y^{(i)}) \log(1-\hat{y}^{(i)})]$

The 1st formula besides the title in the image is actually a squared function [2 got erased]

This formula isnt feasible. The next formula below the title is used.

It computes error for single training eg., for entire training set, cost function is used.

*Cost function* is the avg of loss functions of the entire training set.

$$\rightarrow z = w^T x + b$$

$$\rightarrow \hat{y} = a = \sigma(\underline{z})$$

$$\rightarrow \mathcal{L}(a, y) = -(y \log(a) + (1 - y) \log(1 - a))$$

## Cost function [ $J(w, b)$ ]

### Gradient Descent

Recap:  $\hat{y} = \sigma(w^T x + b)$ ,  $\sigma(z) = \frac{1}{1+e^{-z}}$  ←

$$\underline{J(w, b)} = \frac{1}{m} \sum_{i=1}^m \mathcal{L}(\underline{\hat{y}^{(i)}}, \underline{y^{(i)}}) = -\frac{1}{m} \sum_{i=1}^m y^{(i)} \log \hat{y}^{(i)} + (1 - y^{(i)}) \log(1 - \hat{y}^{(i)})$$

Want to find  $w, b$  that minimize  $J(w, b)$

The formula given above the graph is of cost function, its avg of loss function

The graph represents a convex function whose height equals the cost function and its Global optimum gives values of  $w$  and  $b$  that help to minimise the  $J(w,b)$

The red coloured point that is drawn down is due to iterations of gradient descent

G.d. is used to reduce the initial points of  $w$  and  $b$  to the global optimum

## Gradient Descent

update  $w$

$$w := w - \alpha \frac{dJ(w)}{dw}$$

learning rate  $\alpha$

"dw"

$$w := w - \alpha dw$$

$\frac{dJ(w)}{dw} = ?$

$J(w,b)$

$$w := w - \alpha \frac{\partial J(w,b)}{\partial w}$$

$$b := b - \alpha \frac{\partial J(w,b)}{\partial b}$$

"partial derivative"  $J$

$\frac{\partial J(w,b)}{\partial w}$

$\frac{\partial J(w,b)}{\partial b}$

$dw$

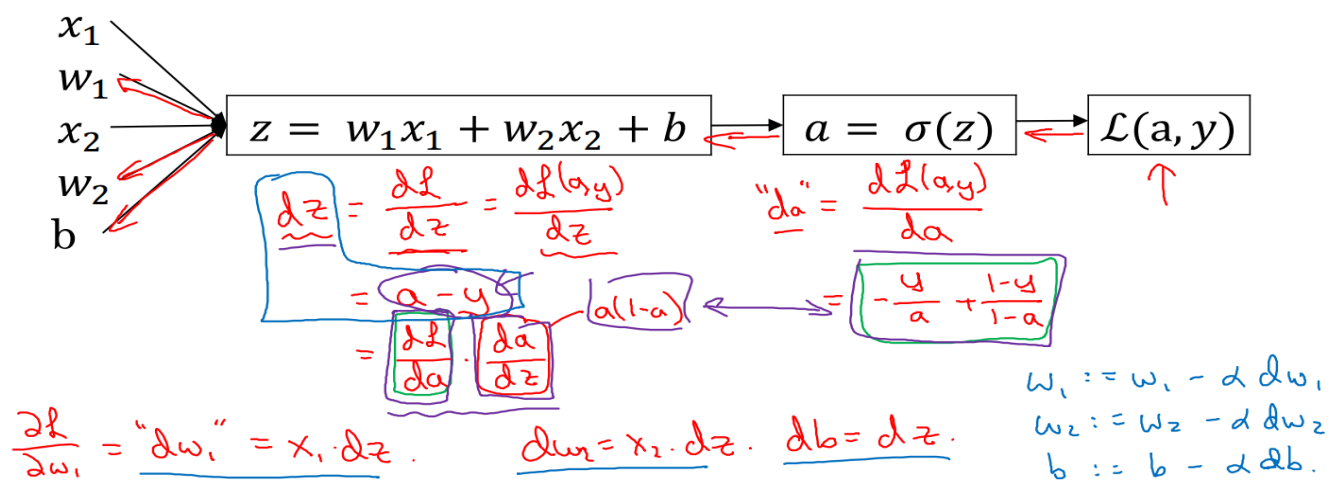

$db$

We also need to update  $w$ ;  $w$  updated  $w$  is denoted by " $w$ :" the variable in code for the derivative term

The Variable in code for the derivative present in the  $w$  formula is  $dw$

$dw$  or  $dJ/dw$  is the slope [ height/width =  $J/w$  ] which if positive initially makes gradient descent to decrease.

$J$  is a function of  $w$  and  $b$  as per the original formula, here, if  $J$  is supposed to be a function of  $b$  too for that we use partial derivative of  $J$

Remember derivative of loss wrt  $z$  is  $a-y$

The derivatives of loss remain constt, like formulae do.

In the below pic it is shown which variables vary for  $m$  no. of training examples [ subscript  $i$  associated all variables ]

$$\begin{aligned} J(w, b) &= \frac{1}{m} \sum_{i=1}^m \ell(a^{(i)}, y^{(i)}) && (x^{(i)}, y^{(i)}) \\ \rightarrow a^{(i)} = \hat{y}^{(i)} &= \sigma(z^{(i)}) = \sigma(w^T x^{(i)} + b) && \underline{dw_1^{(i)}}, \underline{dw_2^{(i)}}, \underline{db^{(i)}} \end{aligned}$$
  
$$\underline{\frac{\partial}{\partial w_1} J(w, b)} = \frac{1}{m} \sum_{i=1}^m \underbrace{\frac{\partial}{\partial w_1} \ell(a^{(i)}, y^{(i)})}_{\underline{dw_1^{(i)}} - (x^{(i)}, y^{(i)})}$$

The above figure gives the formula of loss for  $m$  training egs. and its derivative for some parameter  $w_1$

Below we initialise  $J$ ,  $w$  and  $b$  to 0 and the following figure shows how to implement the formulas for the  $m$  training examples

$$\begin{aligned}
 & J=0; \underline{dw_1}=0; \underline{dw_2}=0; \underline{db}=0 \\
 & \rightarrow \text{For } i=1 \text{ to } m \\
 & \quad z^{(i)} = w^T x^{(i)} + b \\
 & \quad a^{(i)} = \sigma(z^{(i)}) \\
 & \quad J += -[y^{(i)} \log a^{(i)} + (1-y^{(i)}) \log(1-a^{(i)})] \\
 & \quad \underline{dz^{(i)}} = a^{(i)} - y^{(i)} \\
 & \quad \begin{aligned}
 & \quad dw_1 += x_1^{(i)} dz^{(i)} \\
 & \quad dw_2 += x_2^{(i)} dz^{(i)} \\
 & \quad db += dz^{(i)}
 \end{aligned} \\
 & \quad J /= m \leftarrow \\
 & \quad dw_1 /= m; dw_2 /= m; db /= m. \leftarrow
 \end{aligned}$$

$$dw_1 = \frac{\partial J}{\partial w_1}$$

$$w_1 := w_1 - \alpha \underline{dw_1}$$

$$w_2 := w_2 - \alpha \underline{dw_2}$$

$$b := b - \alpha \underline{db}$$

Vectorization

this is applicable only works for small datasets.

In the above fig, 2 for loops run -

1 for the Training eg

Another for the parameters w1 and w2

Even though in neural networks we use *vectorisation* instead of for loops

After W(s) are found, we update them

W(s) are accumulative variables which's why there are no subscripts with them

derivative dz\_i helps calculate the loss function for each training eg

## Vectorisation

Colab nbk for vectorisation function, diff bw this function and normal for loop [execution time]

☞ **Untitled14.ipynb**

### Logistic regression derivatives

The image shows a handwritten code snippet for calculating derivatives in a logistic regression model. The code is annotated with green boxes and arrows indicating vectorization changes. The original code (crossed out) used a for loop to calculate derivatives for each data point. The modified code uses vectorized operations with `np.zeros` and `np.dot` to calculate the derivatives for all data points at once. The annotations include `dw = np.zeros((n_x, 1))`, `dw += x(i) dz(i)`, and `dw /= m`.

```
J = 0, dw1 = 0, dw2 = 0, db = 0    dw = np.zeros((n_x, 1))
→ for i = 1 to m:
    z(i) = wTx(i) + b
    a(i) = σ(z(i))
    J += -[y(i) log a(i) + (1 - y(i)) log(1 - a(i))]
    dz(i) = a(i) - y(i)
    dw1 += x1(i) dz(i)    n_x = 2    dw += x(i) dz(i)
    dw2 += x2(i) dz(i)
    db += dz(i)
J = J/m, dw1 = dw1/m, dw2 = dw2/m, db = db/m
dw /= m
```

**The above** fig is for calculating derivatives by vectorisation  
The original version was by non-vec, we then cancelled the areas, where np functions and other vectorisation tactics can be used

Modifications-

Initialisations replaced with `np.zeros`

The for loop for `j=1..n_x` and `w[j] += x_1[i]*dz[i]`

**is replaced by** `dw += x[i]*dz[i]`

So, now only 1 for loop present [ was 2 earlier ]

At the end, `dw/=m` replaces `dw_1/=m` and `dw2` too

# Vectorizing Logistic Regression

$$\begin{aligned}
 &\rightarrow \boxed{z^{(1)} = w^T x^{(1)} + b} \quad \boxed{z^{(2)} = w^T x^{(2)} + b} \quad \boxed{z^{(3)} = w^T x^{(3)} + b} \\
 &\rightarrow \boxed{a^{(1)} = \sigma(z^{(1)})} \quad \boxed{a^{(2)} = \sigma(z^{(2)})} \quad \boxed{a^{(3)} = \sigma(z^{(3)})}
 \end{aligned}$$
  

$$\begin{aligned}
 \underline{\underline{X}} &= \begin{bmatrix} x^{(1)} & x^{(2)} & \dots & x^{(m)} \\ | & | & & | \\ | & | & & | \\ | & | & & | \end{bmatrix} \quad \begin{matrix} (n_x, m) \\ \mathbb{R}^{n_x \times m} \end{matrix} \quad \begin{matrix} \xrightarrow{[ \quad ]} \\ w^T \end{matrix} \begin{bmatrix} x^{(1)} & x^{(2)} & \dots & x^{(m)} \\ | & | & & | \\ | & | & & | \\ | & | & & | \end{bmatrix} \\
 \underline{\underline{Z}} &= \begin{bmatrix} z^{(1)} & z^{(2)} & \dots & z^{(m)} \\ | & | & & | \\ | & | & & | \\ | & | & & | \end{bmatrix} = \underbrace{w^T X}_{1 \times m} + \underbrace{[b \ b \dots b]}_{1 \times m} = \begin{bmatrix} w^T x^{(1)} + b \\ w^T x^{(2)} + b \\ \dots \\ w^T x^{(m)} + b \end{bmatrix} \\
 &\rightarrow \underline{\underline{Z}} = \text{np.dot}(w.T, X) + \underline{\underline{b}} \quad \begin{matrix} \mathbb{R}^{(1,1)} \quad \mathbb{R} \end{matrix} \quad \text{"Broadcasting"} \\
 \underline{\underline{A}} &= \begin{bmatrix} a^{(1)} & a^{(2)} & \dots & a^{(m)} \\ | & | & & | \\ | & | & & | \\ | & | & & | \end{bmatrix} = \sigma(\underline{\underline{Z}})
 \end{aligned}$$

Instead of operating individually on  $z_1, z_2, z_3$ , for  $a(s)$

We use the  $Z$  that equals dot product of  $w^T$  and  $x$  and adds  $b$
